

ORIGINAL ARTICLE

Effects of zinc and cadmium ions on cell growth and production of coumarins in cell suspension cultures of *Angelica archangelica* L.

Vliv zinečnatých a kademnatých iontů na růst a produkci kumarinů v suspenzní kultuře *Angelica archangelica* L.

Summary

The plant cell may respond to the excess of heavy metals in its environment by various mechanisms, including enhanced biosynthesis of secondary metabolites. In this study, zinc (0 to 1500 μM) and cadmium ions (0 to 100 μM) were tested as potential elicitors of the production of coumarins in angelica cell suspension cultures. In addition, the toxicity of both metals was assessed by evaluating their effect on cell growth (characterized by fresh and dry biomass at the end of a two-week subculture). It has been found that fresh biomass was not influenced up to zinc concentrations of 150 and 300 μM in the dark-grown and light-grown cultures, resp. Then it declined with an increasing zinc level. Zinc at 1500 μM diminished it by 54% and 24% in the dark-grown and light-grown cultures, resp. Dry biomass was influenced in a similar way. Zinc at 1500 μM reduced dry cell weight by 30% and 20% in cultures in the dark and in the light, resp. Cadmium ions did not affect fresh and dry weights of cells up to concentrations of 10 μM and 50 μM in cultures in the dark and in the light, resp. Toxic concentrations of cadmium are by an order of magnitude lower than those of zinc. Cadmium at 50 μM reduced fresh and dry cell weights by 66% and 59%, resp., in the dark-grown cultures. Cadmium at 100 μM caused a decrease in fresh and dry biomass by 40% and 44%, resp., in the light-grown cultures. Neither zinc nor cadmium improved production of coumarins.

Souhrn

Rostlinná buňka může reagovat na nadbytek těžkých kovů ve svém prostředí různými mechanismy, včetně zvýšené biosyntézy sekundárních metabolitů. V této práci byly testovány zinečnaté (0 až 1500 μM) a kademnaté (0 až 100 μM) ionty jako potenciální elicitory produkce kumarinů v suspenzních kulturách anděliky lékařské. Navíc byla posuzována toxicita obou kovů hodnocením jejich účinku na buněčný růst (charakterizován čerstvou a suchou hmotností biomasy na konci čtrnáctidenní kultivace). Bylo zjištěno, že čerstvá hmotnost nebyla ovlivněna zinkem do koncentrace 150 μM u kultur ve tmě a 300 μM na světle. Potom klesala s rostoucí hladinou zinku. Zinek v koncentraci 1500 μM ji snížil v kulturách rostoucích ve tmě o 54 %, za světla o 24 %. Suchá hmota byla ovlivněna podobným způsobem. Zinek v koncentraci 1500 μM redukoval suchou hmotnost při kultivaci ve tmě o 30 %, na světle o 20 %. Kademnaté ionty neovlivnily čerstvou a suchou hmotnost buněk u kultur ve tmě do koncentrace 10 μM , na světle do 50 μM . Toxické koncentrace kadmia jsou o řád nižší než u zinku. Kadmium v koncentraci 50 μM snížilo čerstvou hmotnost buněk o 66 %, suchou o 59 % v kulturách ve tmě. Kadmium v koncentraci 100 μM redukovalo čerstvou hmotnost buněk o 40 %, suchou o 44 % v kulturách na světle. Zinečnaté ani kademnaté ionty nezvýšily produkci kumarinů.

Klíčová slova: *Angelica archangelica* L. • suspenzní kultura • růst • kumariny • zinek • kadmium • elicitace • světelné podmínky • sekvenční injekční analýza

Introduction

Plant secondary metabolites are economically important as drugs, flavours and fragrances, pigments, pesticides, and food additives^{1, 2}. In recent years the evolving commercial importance of secondary metabolites has resulted in a great interest in the possibility of altering the production of bioactive compounds by means of plant tissue culture technology³.

Table 1. Examples of plant cell cultures used for the commercial production of high-value secondary metabolites ⁴⁾.

Species	Metabolite	Application
<i>Taxus</i> spp.	paclitaxel	anticancer
<i>Lithospermum erythrorhizon</i>	shikonin	anti-inflammatory, anticancer
<i>Coptis japonica</i>	protoberberines	antibiotic, anti-inflammatory
<i>Thalictrum minus</i>		
<i>Coleus blumei</i>	rosmarinic acid	anti-inflammatory
<i>Panax ginseng</i>	ginseng	dietary supplement
<i>Echinacea purpurea</i>	polysaccharides	anti-inflammatory, immunostimulant
<i>Echinacea angustifolia</i>		
<i>Duboisia</i> spp.	scopolamine	anticholinergic

Some examples of successful commercial processes for supply of pharmaceutically valuable substances are shown in Table 1⁴⁾. However, the *in vitro* production is still facing many biological and biotechnological limitations. One of the obstacles is a low yield of metabolites in plant cell cultures. Since the major roles of plant secondary metabolites are to protect plants from attack by insect, herbivores and pathogens, or to survive other biotic and abiotic stresses, some strategies based on this principle have been developed to improve the yield of such plant secondary metabolites *in vitro*⁵⁾. Plants as well as plant cell cultures show physiological and morphological responses to biological, physical, or chemical stress factors which are known as elicitors^{3, 6)}. The elicitors include, e.g., components of microbial cells, heavy metal ions, hyperosmotic stress, and ultraviolet radiation, as well as the signalling compounds in plant defence responses such as salicylic acid and methyl jasmonate^{7–9)}. The modes of elicitor action are complex. Moreover, since little is known about the biosynthetic pathways of most secondary metabolites, the effect of an elicitor on a plant cell culture cannot easily be predicted¹⁰⁾. Therefore the majority of elicitation approaches are empirical and the optimum conditions have to be determined experimentally for each system in particular.

Production of secondary metabolites has been investigated in cell cultures derived from many plant species in the family *Apiaceae* (*Umbelliferae*), e.g., *Petroselinum crispum* (coumarins)¹¹⁾, *Anethum graveolens* (flavonoids)¹²⁾, *Pimpinella anisum* (coumarins)¹³⁾, *Daucus carota* (anthocyanins)¹⁴⁾, *Ammi majus* (coumarins)¹⁵⁾, *Anthriscus sylvestris* (lignans)¹⁶⁾, and *Glehnia littoralis* (anthocyanins and coumarins)¹⁷⁾.

We report here the effects of zinc and cadmium sulphates as potential elicitors on cell growth and production of coumarins in *Angelica archangelica* cell suspension cultures.

Experimental part

Chemicals

2,4-dichlorophenoxyacetic acid, 6-benzylaminopurine, and agar (plant cell culture tested, Sigma, Praha, Czech Republic); scopoletin (analytical standard, Fluka, Praha, Czech Republic); zinc sulphate, cadmium sulphate, sodium phosphate dibasic, and potassium phosphate monobasic (*p.a.*, Lachema, Brno, Czech Republic).

Instruments

A PS 20A autoclave (Chirana, Brno, Czech Republic); a roller (Vyvojové dílny, Academy of Sciences of the Czech Republic, Praha, Czech Republic); a 200S analytical scale (Sartorius, Göttingen, Germany); a laboratory centrifuge MPW 342 (MPW Med. instruments, Warsaw, Poland); a laboratory shaker KS 501 (IKA Laborotechnik, Staufen, Germany); a peristaltic pump (Alitea Instruments, Seattle, U.S.A.); an eight position selection valve (Vici Valco Instruments, Brockville, Canada); and a FS 970 fluorescence detector (Schoeffel Instrument Corp., Westwood, U.S.A.).

Cell suspension cultures and culture conditions

Tissue cultures of *Angelica archangelica* were derived from a bud of an in spring sprouting one-year old plant grown in the Botanical Garden of Faculty of Pharmacy in Hradec Králové. Callus cultures were established from the bud meristem and maintained by subculturing every five weeks on Murashige and Skoog medium¹⁸⁾ supplemented with 2 mg l⁻¹ 2,4-dichlorophenoxyacetic acid, 0.4 mg l⁻¹ benzylaminopurine, 30 g l⁻¹ sucrose, and 8 g l⁻¹ agar. The pH of all media was adjusted to 5.7 before autoclaving at 121 °C for 15 min. Cell suspension cultures were initiated from friable calluses in the same medium devoid of agar. They were agitated in 250 ml flasks containing 30 ml of the medium on a roller apparatus at 8 rpm, incubated at 25 ± 1 °C under a 16/8 light/dark photoperiod or in the dark, and subcultured every two weeks.

For testing the effects of metal ions, the cultures were cultured in Murashige and Skoog media supplemented with an appropriate concentration of zinc sulphate (0, 30, 60, 150, 300, 600, and 1500 µM) or cadmium sulphate (0, 0.1, 0.5, 1, 2, 5, 10, 50, and 100 µM). After 14 days, the cultures were harvested, and the cell growth and production of coumarins were evaluated. All experiments were carried out in triplicate and repeated three times.

Analytical procedures

Cells were separated from the culture medium by vacuum filtration using a Buchner funnel with filter paper. For evaluation of the culture growth, filtered cells were washed with distilled water, weighed for fresh weight determination, and then dried at 60 °C to obtain dry weight.

Coumarins in cells and in the culture medium were quantified fluorometrically by sequential injection

Fig. 1. *Angelica archangelica* cell suspension cultures cultured under heterotrophic conditions. Photomicrograph of cell clusters at a magnification of 200x and 400x (the scale is 50 and 20 μm , resp.).

Fig. 2. *Angelica archangelica* cell suspension cultures cultured under photomixotrophic conditions. Photomicrograph of cell clusters at a magnification of 200x and 400x (the scale is 50 and 20 μm , resp.).

analysis as described in detail previously¹⁹). In brief, the powdered dry cells were extracted three times (always 15 min) by a mixture of equal volumes of methanol and 0.066 M phosphate buffer (pH 6) by shaking at 150 rpm on an orbital shaker at laboratory temperature. The extracts were pooled, adjusted to 25 ml with the extraction mixture, centrifuged at 3.000 rpm for 10 min, and analysed. The culture media were analysed direct. The conditions of the sequential injection analysis were as follows – a carrier stream: water; flow rate: 3 ml/min⁻¹; sample volume: 40 μl ; volume of 0.066 M phosphate buffer (pH 6): 100 μl ; a 1.5 ml mixing coil; excitation wavelength: 345 nm; and emission wavelength: a cut-off emission filter transparent at ≥ 390 nm. The contents of coumarins were expressed as scopoletin (mg l⁻¹ in the medium and mg g⁻¹ dry weight in the cells).

Experimental data were statistically analysed using a one-way analysis of variance (ANOVA), followed by Tukey's multiple comparison test. Differences at $p < 0.05$ were considered as statistically significant.

Results and discussion

Zinc belongs to the essential trace elements, whereas cadmium has no known biological function in plants^{20, 21}. Zinc participates in several metabolic processes such as

protein synthesis, enzyme activation, and metabolism of carbohydrates, lipids or nucleic acids; and it is an integral part of transcription factors controlling cell proliferation and differentiation²²). Zinc is suggested to have a stabilizing and protective effect against reactive oxygen species mediated oxidative and peroxidative damage in cells²²). Zinc and cadmium can be toxic to plants. The toxic dose depends on the ion concentration and plant species²⁰). There are even plants thriving in metal-enriched environments. Certain plant species, called hyperaccumulators, accumulate and tolerate unusually large amounts of metals compared to other plants and the ambient metals concentration, without symptoms of toxicity^{20, 23}). Zinc and cadmium hyperaccumulators are, for instance, *Pistia stratiotes*²³), *Thlaspi caerulescens*²⁴), *Arabidopsis halleri*²⁵), and *Sedum alfredii*²⁶).

As mentioned above, heavy metal salts may be employed to stimulate production of secondary metabolites in plant tissue cultures^{27, 28}). We have tested zinc and cadmium ions in a wide range of concentrations (zinc up to 1500 μM , cadmium up to 100 μM , based on preliminary experiments; higher concentrations were lethal for the culture) as potential elicitors of production of coumarins in angelica cell suspension cultures. In addition, the toxicity of zinc and cadmium for the culture was assessed by evaluating their effects on cell growth,

Table 2. Effects of zinc ions on cell growth and production of coumarins in *Angelica archangelica* cell suspension cultures. Values are means \pm standard deviations ($n = 3$). Asterisks denote significant differences between control ($30 \mu\text{M Zn}^{2+}$ as in standard Murashige and Skoog medium) and Zn-treated cultures, $P < 0.05$.

which was characterized by the fresh and dry weights of cells (the most widely growth parameters used) at the end of a two-week subculture. The cultures were cultured in the dark or in the light because light conditions are an important environmental factor involved not only in the regulation of plant growth and organogenesis, but also in the biosynthesis of primary and secondary metabolites^{29, 30}.

As shown in Figs. 1 and 2, cell cultures of *Angelica archangelica* grew as a homogeneous suspension consisting of cell clumps with the diameter of about 150 μm . There were no morphological differences between cultures cultured under heterotrophic and photomixotrophic conditions. No cell differentiation or organogenesis was observed.

Effects of zinc ions on angelica cell suspension cultures are presented in Table 2. Zinc sulphate is a component of the basal Murashige and Skoog medium (MS medium) at a concentration of 30 μM . Fresh biomass was not significantly influenced in a range of zinc concentrations from 0 (MS medium without zinc sulphate) to 150 and 300 μM in the dark-grown and light-grown cultures, respectively. Then it declined with an increasing zinc level. Zinc ions at 1500 μM

diminished it by 54% and 24% in the dark-grown and light-grown cultures, respectively, in comparison to control cultures in the standard MS medium. Dry biomass was influenced in a similar way. Zinc ions at 1500 μM reduced dry cell weight by 30% and 20% in cultures cultured in the dark and in the light, respectively. As for production of coumarins, elimination of zinc from the medium as well as its concentrations up to 300 μM did not markedly affect the levels of coumarins in cells and medium in the dark-grown and light-grown cultures. Higher zinc concentrations decreased the contents of coumarins in cells under both light conditions; in the medium, coumarins declined correspondingly in the cultures cultured in the light, but rose in those in the dark, which could be due to damages in the cell membrane or to cell lysis, as a consequence of zinc toxicity. In the same way as in angelica cell cultures, fresh and, similarly to a lesser extent, dry weights of cultured tomato cells decreased with increasing zinc concentrations from 500 to 5000 μM , markedly when zinc concentration was higher than 1000 μM ²⁹. Toxicity of zinc was investigated and compared in cell suspension cultures of *Arabidopsis halleri*, a zinc hyperaccumulator, and *Mesembryanthemum crystallinum*, a plant shown to

be sensitive to zinc: the dry cell weight did not change statistically with increasing zinc concentration in cultures of the former exposed to zinc concentrations up to 1000 μM , whereas cultures of the latter showed inhibition of growth in the presence of increasing concentrations of zinc, considerably from the concentration of 500 μM ²⁵. Zinc ions at concentrations from 300 to 900 μM could cause any significant increase in the overall productivity of the betalains in hairy root cultures of *Beta vulgaris*³². A slightly positive effect on the production of betalains and no influence on the growth had zinc in cell suspension cultures of *Beta vulgaris*³³. Increased concentration of zinc did not influence cell growth and inhibited camptothecin biosynthesis in *Camptotheca acuminata* suspension cultures²⁷. Zinc ions decreased biosynthesis of α -tocopherol and improved pigment production in *Carthamus tinctorius* cell suspension cultures²⁸. Zinc did not significantly affect the growth of *Papaver bracteatum* cell cultures or alkaloid yields³⁵. Zinc seems to be not too suitable for elicitation of secondary metabolites in plant tissue cultures.

The influence of cadmium ions on angelica cell suspension cultures is shown in Table 3. The presence of cadmium ions did not affect fresh and dry weights of cells up to concentrations of 10 μM and 50 μM in cultures in the dark and in the light, respectively. Toxic concentrations of cadmium are by an order of magnitude lower than those of zinc. Cadmium ions at 50 μM reduced fresh and dry cell weights by 66% and 59%, respectively, in cultures cultured in the dark. Cadmium at 100 μM caused a decrease in fresh and dry biomass by 40% and 44%, respectively, in the light-grown cultures. With regard to biosynthesis of coumarins, addition of cadmium ions to the culture medium did not improve or decrease the production of coumarins in *Angelica archangelica* cell suspension cultures. The findings are in agreement with those in the whole plant cultures of *Centella asiatica*, where the asiaticoside production declined in the presence of cadmium ions³⁶. Cadmium from 1 to 500 μM caused growth depression depending on its concentration in whole plant cultures of *Dionaea muscipula*; on the other hand, an increasing cadmium level led to enhanced anthocyanin biosynthesis³⁷. An increase in growth and, on the contrary, an inhibition of growth occurred in *Nicotiana tabacum* cell suspension cultures grown at 100 and 200 μM cadmium, respectively³⁸. The dry weight accumulation in the suspension culture of *Catharanthus roseus* treated with 50 μM cadmium was not different from that of the control culture; cadmium concentrations up to 400 μM lowered culture dry weight, and concentrations higher than 600 μM were lethal for the culture³⁹. Cadmium ions at a concentration of 25 μM reduced the dry biomass yield by about 50% and increased production of tanshinones about 11-fold in cell suspension cultures of *Salvia miltiorrhiza*⁸. Production of coumarins in angelica cell cultures was not improved by cadmium, whereas that of gymnemic acid, ajmalicine, and sanguinarine in suspension cultures of *Gymnema sylvestre*²⁸, *Catharanthus roseus*³⁹, and *Papaver somniferum*⁴⁰, respectively, was stimulated by cadmium treatment.

There are many reports concerning the influence of zinc and cadmium on plants^{41–47}. Various mechanisms of how a plant cell reacts to an excess of essential heavy metal ions, e. g. zinc, or the toxic ones that do not play a role in metabolism, e. g. cadmium, were described. They include an increase in the activities of antioxidant enzymes³⁸ and enhanced biosynthesis of amino acids (such as histidine⁴⁸ and cysteine³⁷), glutathione²¹, phytochelatin⁴⁹, metallothioneins⁴⁸, organic acids (such as citrate and malate)⁵⁰, and secondary metabolites^{33, 39}. The latter mentioned way of plant cell reaction attracts research attention because of its possible use for stimulation of secondary metabolism in plant tissue cultures. However, particular mechanisms occur to a different extent depending on the plant species and the kind of heavy metal. On the one hand, several of them, at various intensities, may run together – side by side or one after another. On the other hand, some of them can be involved weakly or not at all. Based on our results, increased biosynthesis of secondary metabolites does not participate in response of angelica cultures to zinc and cadmium treatment. It can be concluded that zinc and cadmium ions are not suitable as elicitors enhancing the production of coumarins in *Angelica archangelica* cell suspension cultures.
