SUMMARY

Aim: To determine the effect of repeated intravitreal injections of aflibercept on the corneal endothelium in patients with diabetic macular edema (DME) and macular edema due to retinal vein occlusion (RVO).
Methods: In a prospective study conducted between January 2021 and November 2023, a total of 87 treatment-naive eyes with DME and RVO were evaluated. The exclusion criteria were surgery or laser intervention during the follow-up period, contact lens wear, cataract surgery in the last 6 months, dystrophy, or other corneal condition that may cause endothelial damage. In addition to routine examinations on the day of application, we also measured the corneal endothelium using specular microscopy on the 1st, 4th and 8th day of injection. We evaluated 4 parameters: endothelial cell density (CD), hexagonality (HEX), coefficient of variability (CV) and central corneal thickness (CCT). First of all, we evaluated the entire cohort of eyes, and then divided it according to 2 criteria; the diagnosis into DME/RVO and according to the lens status into phakic/pseudophakic eyes.
Results: A total of 87 eyes of 68 patients were evaluated. The average age of the patients at the time of diagnosis was 66.8 ±9.3 years. Within the cohort 51 (59%) eyes were phakic and 36 (41%) pseudophakic. A total of 61 (70%) eyes with a diagnosis of DME were treated, and 26 (30%) with RVO. During the follow-up, there were no significant changes in the average values of CD, HEX, CV, CCT due to aflibercept treatment, either in the whole group or in subgroups according to diagnosis or lens condition.
Conclusions: The results of this study suggest that intravitreal administration of aflibercept in patients with DME and RVO did not have an impact on corneal endothelial parameters, including CCT, HEX, CD and CV. These parameters were measured using endothelial microscopy during an 8-injection observation period.
Key words: aflibercept, corneal endothelium, endothelial cells, antiVEGF, specular microscope

INTRODUCTION

The endothelium is one of 6 layers of the cornea, and is formed by one layer of hexagonal shape cells [1,2]. It ensures the active transport of water out of the cornea, and is thereby responsible for the transparency, constant hydration and stable optical power of the cornea [3]. The density of the endothelial cells decreases with age by approximately 0.6% per year, from a number of 3400 cells/mm^2 at the age of 15 years to approx. 2300 cells/mm^2 at the age of 85. The physiological density of endothelial cells is stated as the number of 2000–3000 cells/mm^2 [4]. The principle of non-contact specular microscopy is to display the corneal endothelium with the use of a mirror reflection on the interface between the endothelium and the anterior chamber fluid. This is achieved by white light and a microscope with powerful enlargement. The specular microscope measures corneal thickness, and automatically segments and counts the endothelial cells. The instrument generates various indexes, which assist in the diagnosis and treatment of the cornea, for example cell density (CD), coefficient of variability (CV), hexagonality (HEX) and central corneal thickness (CCT) [5]. Studies have confirmed the presence of vascular endothelial growth factors (VEGF) and its receptors on the epithelium, stroma and corneal endothelium [6–10].

Intravitreally applied pharmaceuticals are eliminated from the eye by two paths: posteriorly via the blo-

od-retinal barrier, and anteriorly by means of drainage of the chamber fluid. However, several experimental studies have demonstrated that antiVEGF molecules are practically completely eliminated by the anterior pathway [11–13]. Aflibercept (Eylea®, Bayer) is a fusion protein which contains fragments of domains of human VEGF receptors 1 and 2, bind-ing to the Fc fragment of human IgG1. It functions as a soluble substitute receptor, which binds VEGF-A and placental growth factor (PlGF), and thereby inhibits their binding to the receptor [14]. The pharmacokinetic profile of intravitreal application of 2.0 mg/0.05 ml aflibercept in humans has not yet been definitively clarified, but Do et al. have confirmed that the half-life of aflibercept in the chamber fluid following a single intravitreal application was 11 days in patients with age-related macular degeneration (AMD) [15]. Bevacizumab was detected in the anterior chamber even as long as one month after intravitreal application [12]. Our objective was to examine whether repeated intravitreal applications of aflibercept may adversely affect the endothelium and corneal thickness in patients with diabetic macular edema (DME) and macular edema upon a background of retinal vein occlusion (RVO).

MATERIAL AND METHOD

The prospective study conducted between January 2021 and November 2023 included a total of 87 eyes (68 patients) with a diagnosis of DME and RVO. All the patients were treatment-naive, and had been indicated for intravitreal treatment with aflibercept. The exclusion criteria were other ocular surgical or laser procedure during the follow-up period, contact lens wear, dystrophy or other corneal condition that may cause changes to the endothelium. The included pseudophakic eyes were more than 6 months after cataract surgery. On the day of application, we measured as standard best corrected distance visual acuity (BCVA) with the ETDRS optotype, intraocular pressure using a non-contact tonometer, anterior and posterior segment in mydriasis and central retinal thickness (CRT) on the optical coherence tomography (OCT). In addition to these routine examinations, on the day of the 1st, 4th and 8th injection we also ex-amined the corneal endothelium (Fig. 1, 2). We performed endothelial microscopy with Nidek CEM-530 (Tokyo, Japan). We scanned the central cornea a size of 0.55 x 0.25 mm with the instrument configured in an automatic mode with auto-tracking. We conducted 5 measure-ments and evaluated the best quality scan. We evaluated 4 parameters: CD, HEX, CV and CCT. We then injected 0.05 ml of aflibercept intravitreally into the patient under sterile asep-tic conditions under topical anesthesia. The results were statistically analysed with the use of descriptive statistics, a Chi-squared test and a t-test, the level of significance was set at $p = 0.05$.

RESULTS

Table 1 presents the basic demographic data. A total of 87 treatment-naive eyes of 68 patients were included in the evaluation. The average age of the patients at the time of diagnosis was 66.8 ±9.3 (33–87) years. The ratio of men to women was 52 (60%): 35 (40%). Of the total number of 87 eyes, 51 (59%)

Figure 1. Corneal specular microscopy of 68-year-old pseudophakic patient with macular edema due to retinal vein occlusion on left eye on day of 1st, 4th and 8th application

were phakic and 36 (41%) pseudophakic. A total of 61 (70%) were treated with a diagnosis of DME, and 26 (30%) with a diagnosis of RVO; of the latter group 15 (17%) patients had branch RVO and 11 (13%) central RVO. The mean value of glycated hemoglobin in patients with diabetes mellitus (DM) was 7.6 ±0.7% (5.9–9.9) DCCT, and 54 eyes (89%) had DME upon a background of type 2 DM.

Mean BCVA of all the patients on the day of the 1st injection was 53 ±12 letters of ETDRS. A significant improvement to 60 ±12 took place on the day of the 4th application, and again on the day of the 8th application to 62 ±12 letters of ETDRS, ($p < 0.001$ for both in comparison with the 1st injection). Identically significant improvements also took place upon the division of the eyes according to diagnosis, in the group with DME (55 ±11; 60 ±11; 62±13) and RVO (49 ±13; 58 ±13; 61 ±12) letters of ETDRS.

Mean CRT measured on spectral OCT on the day of the 1st injection of aflibercept was 565 ±151μm. On the day of the 4th application there was a significant reduction to 347 ±92 μm and on the day of the 8th application to 322 ±95 μm, ($p < 0.001$ for both in comparison with the 1st injection). Significantly significant improvements were achieved also upon the division of the eyes according to diagnosis, in the group with DME (538 ±127; 367 ±83; 324 ±90) and RVO (629 ±185; 300 ±95; 319 ±107) μm.

We evaluated 4 parameters of the corneal endothelium measured with the aid of endothelial microscopy: CD, CV, CCT and HEX. First of all we evaluated the entire cohort of eyes and subsequently divided it according to 2 criteria; according to diagnosis into DME/RVO and according to the condition of the lens into phakic/pseudophakic eyes (Table 2).

Mean CD in all eyes on the day of the 1st application was 2669 ±346 bb/mm^2. On the day of the 4th (2642 ±369

p-value indicated the statistical significance of the difference between the 1st application values, DME – diabetic macular edema, RVO – retinal vein occlusion

phakic (2731 ±334; 2730 ±343; 2696 ±363) and pseudophakic eyes (2583 ±348; 2520 ±372; 2634 ±371) bb/mm^2, but no changes of endothelial cell density took place at the time due to the influence of the injections in the subgroups.

During the course of the follow-up period we did not record any significant change of the mean value of CV in all eyes (30 ±5; 31 ±4; 31 ±4)%, or a change of HEX of the endothelial cells (68 ±4; 68 ±4; 66 ±7)% or a change of mean CCT (564 ±32; 564 ±33; 562 ±28) µm. We also did not confirm any mutual differences in HEX and CV between the subgroups according to diagnosis or state of the lens. The only significant change in CCT was recorded in the group with DME, in terms of comparison of CCT on the day of the 8th application in comparison with the 1st application (from 564 to 561 µm, p = 0.042).

Complete follow-up to 8th injection finish 59 (68%) of the original 87 eyes; of which 19 (73%) RVO and 40 (66%) DME eyes. Termination or suspension of treatment before the 8th injection took place due to improvement of the finding (3), exit (1), high level of glycated hemoglobin (10), non-responder with need to switch (9), necessity of pars plana vitrectomy due to epiretinal membrane (2), and for unknown reasons (3).

DISCUSSION

AntiVEGF treatment usually requires repeated intravitreal applications. Studies have demonstrated that VEGF and its receptors are exprimated on the corneal endothelium [6–10]. Experimental animal models have confirmed a certain concentration of antiVEGF molecules in the anterior chamber following their intravitreal application [16], and have also detected a reduction of CD following intracameral application of ranibizumab in rabbits [17]. Based on these facts also, the potential cytotoxic effect of antiVEGF molecules on the corneal epithelium is under investigation.

Papadakou observed the influence of DM alone on the parameters of the corneal endothelium, coming to the conclusion that CD was lower in patients with DM in comparison with a healthy control group [18]. In our cohort we did not record a decrease of CD in patients with DME (2724 ±365; 2684 ±391; 2732 ±399) in comparison with RVO (2541 ±257; 2499 ±297; 2541 ±238) bb/mm^2.

Urban observed the effect of antiVEGF molecules (ranibizumab and aflibercept) on the corneal epithelium in 110 eyes of patients with ARMD. At the end of the six-month observation period, a statistically significant reduction of CD was demonstrated in the group treated with aflibercept. The percentage of hexagonal cells was lower in both groups, and this study also demonstrated a slight increase of polymegathism [19]. It was also demonstrated that ranibizumab causes a minor and insignificant increase of CCT, whereas CCT remained unchanged in the group treated with aflibercept [19]. This is in contradiction with a publication by Chatzi-ralli, who also observed the influence of ranibizumab and aflibercept on the corneal endothelium in 36 patients with DME and determined that these molecules had no influence on the cornea, and after a 12-month follow-up period did not record any changes in CD, HEX, CV and CCT [20]. Joshi et al. did not record any changes on the endothelium in a cohort of 102 eyes during the first month after intravitreal application of ranibizumab, and there was no difference between phakic and pseudophakic eyes [21]. Doguizi also did not demonstrate cytotoxic effects on the endothelium after 4 applications of aflibercept in a cohort of 34 eyes with ARMD [22].

Our results are in accordance with publications that have not confirmed a significant effect on the parameters of the cornea measured on endothelial microscopy in patients with DME and RVO treated with aflibercept after the 8th application. The only significant change in CCT was recorded in the group with DME, specifically upon a of CCT on the day of the 8th application in comparison with the 1st application (from 564 to 561 µm, p = 0.042). With reference to the absence of other changes of the endothelium, we consider this change non-pathological, random and clinically insignificant.

CONCLUSION

Our observations confirm that intravitreal injections of 2.0 mg/0.05 ml of aflibercept in patients with DME and RVO do not affect corneal epithelial parameters, including CCT, HEX, CD and CV. These parameters were evaluated using specular microscopy during an 8-injection observation period.
